TITLE: Circumglobal radiation on a clear felling (microclimate of clear fellings,
Part II)

SOURCE: Meteorologicke zpravy, no. 2, 1965, 41-47

TOPIC TAGS: radioactivity measurement, nuclear physics apparatus, microclima-
tology, forestry, solar radiation

ABSTRACT: Circumglobal radiation in a clear felling was studied with Bellani
spherical pyranometers. The results of radiation measurements were compiled with
reference to solar declination, the presence of clouds and, in winter, the effects
of snow cover. The horizon cover also was measured and the maximum possible time
of solar exposure for individual places in the felling was determined. The results
are compared with similar observations of V. Krecmer in gap cut plots. Orig. art.

SOURCE: Meteorologicke zpravy, no. 5, 1965, 138-143

TOPIC TAGS: snow, climatic condition, microclimatology

ABSTRACT: This partial study is a continuation from the preceding number of this journal. All the measurements were made on a test plot of the Forestry and Game Management Research Institute at Bedovice ($\lambda = 16^{\circ}02' E$, $\phi = 50^{\circ}12'$, 250 meters above mean sea level). The results of investigations on a stripe cut are compared with those of investigations in the forest stand, open area and gap cut area. [JPRS]

(Kak proyavil sebya Terra Sitam na praktike.)

Orig Pub: Chmelarstvi, 1956, 29, No 11, 171-172

Abstract: An experiment on the use of the systematic insecticide Terra Sitam in the Control of aphids on hops. One hundred ml of the preparation were poured into the roots of each plant; in two days the aphids and other pests died. The treated plants grew better and their yield was 8% higher than that of the control plants. The preparation must be used with special caution because of its toxicity.

Title : Some Results of Agrotechnical Experiments with Corn

Orig Pub : Pol'nohospodarstvo, 1956, 3, No 1, 109-117

Abstract : The deciding factor in securing large corn crops in Czechoslovakia is the time of sowing (April 18-30 in the southern regions and May 3-5 in the central regions). The early sowings always produce better results despite possible damage by early frosts and are distinguished by greater drought resistance. Best of all are interrows 70 x 70 cm, 2 plants to a hole in a high-stemmed variety, and 60 x 60 cm, 2 plants

Card : 1/2

TITLE: Effect of temperature on separation of Cr and Mn by ion exchangers

SOURCE: Chemicke zvesti, no. 4, 1965, 294-298

TOPIC TAGS: chromium, manganese, intermolecular complex, chemical separation, ion exchange resin, radioisotope, chemical labelling, radiation chemistry

ABSTRACT:

Separation of Cr and Mn in the form of chloro complexes in 10.5 M HCl at elevated temperatures using anion exchange resin Dowex 2x8 (100-200 mesh) is described. The method was evaluated by using radioisotopes Cr⁵¹ and Mn⁵⁴. The separation coefficient equals 1 at room temperature and increases with increasing temperature. At 70°C it is nearly 4. Above 55°C quantitative separation of Cr and Mn is possible.

TITLE: Chromatographic separation and determination of Cr^{51} , Mn^{54} ,
 Co^{60} and Fe^{59}

SOURCE: Chemicke zvesti, no. 3, 1966, 180-187

TOPIC TAGS: paper chromatography, quantitative analysis

ABSTRACT: The authors developed a method of paper chromatography using Whatman I. chromatographic paper and an acetone- 7 N HCl (90:10) solvent system. A separation with the following R_f values was attained: Cr 0.03, Mn 0.32, Co 0.69, and Fe 0.96. The R_f values are independent from the amount of the isotopic carrier in a wide range. Quantitative determination was made by planimetric evaluation of the radiographic records. Determination threshold of the method is 1.70nCi for Cr^{51} , 0.36nCi for Mn^{54} , 0.12nCi for Co^{60} , and 0.18 nCi for Fe^{59} . The method is suitable for the determination of the metals in biological materials. Orig. art. has: 5 figures, 2 formulas and 3 tables. [Based on authors' Eng. abst.] [JPRS: 36,002]

Title : Yield of resonance fluorescence of atoms

Periodical : Zhur. eksp. i teor. fiz. 28, 253-254, February 1955

Abstract : B. I. Stepanov (DAN SSSR, 99, 971, 1954) studied the statistical interpretation of radiation and system consisting of atoms possessing two energy levels, and showed that the radiation output varies in dependence upon the density of the exciting radiation (this conclusion refers to the total radiation). The authors apply the proposed method to the calculation of the luminescence output of a similar system, e.g. the resonance fluorescence of atoms. They obtain an expression for the quantum output of fluorescence.

Title : Luminescence Yield From a System with Three Energy Levels
Orig Pub : Dokl. AN SSSR, 1955, 105, No 1, 50-53

Abstract : The luminescence yield of a system with three energy levels is calculated and it permits resolving the fundamental problem of whether the value of the energy yield φ can exceed unity. Attempts found in the literature of a thermodynamic proof of the impossibility of $\varphi > 1$ are not satisfactory. The energy yield of luminescence of a system with three levels (Pringsheim model) (Pringsheim, P., Journal of Physics, 1949, 10, 495) is calculated

external extinction does not explain these laws, for it gives an exponential attenuation (mono-molecular) extinction and a dependence of I on E in the form $I \propto E^2$. The stationary brightness and the extinction are calculated for the case, when the holes in the valent zone have a greater probability of returning to the activator level, than of recombining with the localized electrons. A formula is obtained to explain the experimentally observed dependence of I on E in the hyperbolic extinctions. On the basis of the same calculation, an explanation is given for the extinguishing action of Co and Ni and it is shown, that if the extinction is not too strong, when the yield is reduced by merely a factor of several times, the dependence of I on E remains linear.

in detail with allowance for the available thermal radiation in the same way as in the workd listed for a system with two energy levels (Referat Zhur Fizika, 1956, 17898, 23129). A rarefied thin layer of luminescent gas is considered, to make it possible to disregard the reverse reaction of the luminescence on the electron transitions of the radiating systems. It is shown that in the anti-Stokes region Φ can be greater than unity and that this does not contradict the second law of thermodynamics. The energy of a luminescent body together with the excitation energy is transferred to the surrounding medium, the temperature of which is lower than the temperature of the exciting body. This, as indicated by Pringsheim, is analogous to the action of refrigerator. It is shown that it is possible to have "negative" luminescence, i.e., not an excess above the background of thermal radiation, but a deficiency of radiation, having a finite duration.

TITLE: Application of the paramagnetic resonance method to the study
of the activator state in phosphors. (Primeneniye metoda
paramagnitnogo rezonansa dlya issledovaniya sostoyaniya
aktivatora v fosforakh.)

PERIODICAL: "Optika i Spektroskopiya", (Optics and Spectroscopy),
1957, Vol.2, No.4, pp.470-474 (U.S.S.R.)

ABSTRACT: This paper was presented at the 5th Conference on
Luminescence in Tartu, June, 1956. From the nature (or
absence) of the paramagnetic resonance spectrum of a crystal
it is possible to deduce the valency state (and changes of
that valency state) of paramagnetic ions in crystal. This is
more difficult for powders when the paramagnetic absorption
lines may be very broad due to relaxation or anisotropy.
These difficulties are particularly pronounced for the case
of ions whose paramagnetism is due to unpaired d-electrons.
Results are reported for powdered SrS:Eu, SrS:Gd and for
artificial CaF₂:Eu monocrystals. Measurements were carried
out at 9340 Mc/s and at room temperature. The apparatus used
is described in Radiotekhnika i Elektronika, Vol.1, 469,
1956. Some of the present results were reported earlier
(A.A.Manenkov and A.M.Prokhorov, Doklady Akad. Nauk SSSR,

Application of the paramagnetic resonance method to study of the activator state in phosphors. (Cont.)

Vol. 107, 402, 1956). In SrS:Eu and CaF₂:Eu only the Eu²⁺ ion (⁸S_{7/2} state) is effective; Eu³⁺ is non-magnetic. For Eu²⁺ the electron spin is 7/2 and therefore 7 electron transitions are possible due to crystal electric field splitting. In SrS:Eu only one of these transitions M=1/2 ↔ -1/2 was found; the others could not be observed due to anisotropic broadening. This one transition was split into 12 hyperfine structure (h.f.s.) components by the interaction of the nuclear spins of the two Eu isotopes: Eu¹⁵¹ and Eu¹⁵³ with the electron spin. The SrS:Eu paramagnetic spectrum confirms that the europium activator is in the Eu²⁺ state. In the fluorite (CaF₂:Eu) spectrum all 7 electron transitions, each with 12 h.f.s. components, were observed. From the h.f.s. of the paramagnetic spectra of SrS:Eu and CaF₂:Eu the ratio of the magnetic moments of the Eu¹⁵¹ and Eu¹⁵³ nuclei was found to be $\mu_{151}/\mu_{153} = +2.24 \pm 0.03$ nuclear magnetons. Frequency of the absorption lines for CaF₂:Eu monocrystals was found to depend strongly on the crystal orientation with respect to the applied constant magnetic field. This indicates that the crystal electric-field

TITLE: On the recombination interaction of blue and green luminescence centres in the ZnS:Cu phosphors. (O rekombinatsionnom vzaimodeystvii tsentrov goluboy i zelenoy lyuminestsentsii v fosfore ZnS-Cu)

PERIODICAL: "Optika i Spektroskopiya" (Optics and spectroscopy)

1957, Vol.2, No.4, pp.475-479 (U.S.S.R.)

ABSTRACT: This work was carried out with the help of L.A. Vinokurov.

ZnS:Cu has two luminescent bands: green (due to Cu) with an emission maximum at $530 \text{ m}\mu$ and an excitation maximum at $400\text{-}410 \text{ m}\mu$, and blue with emission and excitation maxima at $470 \text{ m}\mu$ and $330\text{-}340 \text{ m}\mu$ respectively. These luminescent bands behave differently: the blue band decays much faster than the green one, and at room temperature the steady-state brightness of the blue band depends on the excitation intensity E more than linearly, while that of the green one is proportional to E or less than linear. This paper presents calculations and experimental results for ZnS:Cu (10^{-6} Cu) samples prepared at 1100°C . An energy band scheme is given in a figure. Theoretical calculations are carried out under the following assumptions: (1) electron and hole densities in the valence band are small; (2) for electrons the probability of recapture is much smaller than the probability of

Card 1/3

51-4-11/25

On the recombination interaction of blue and green luminescence centres in the ZnS:Cu phosphors. (Cont.)

recombination with holes; (3) only a small proportion of the luminescence centres of both types is in the ionized state. The calculations yield the following results. For absorption of exciting light by the blue centres, the steady-state brightness of the blue centres is $I_b \sim E^{3/2}$ and of the green centres $I_g \sim E$ (both for low values of E). At higher values of E we find $I_b \sim E$ and $I_g \sim E^{1/2}$. These formulae are in good semiquantitative agreement with experimental results for the 366 m μ excitation. For excitation in the absorption band of the green centres (436 m μ) theory gives $I_g \sim E$ for all values of E, and $I_b \sim E^n$, where $n = 1$ for lower values of E and $n < 1$ for higher E. This could not be tested experimentally because of mixing of the exciting light with the blue luminescence. Theoretical consideration of decay shows that on excitation of the blue centres, the blue emission decays at first faster than the green but after a time both emissions decay at about the same (hyperbolic) rate. On excitation of the green centres both emissions decay at almost the same rate. Experiments using 366 and 436 m μ excitation respectively confirm theoretical predictions. From experiments at liquid-air temperatures it

Card 2/3

51-4-11/25

On the recombination interaction of blue and green luminescence centres in the ZnS:Cu phosphors. (Cont.)

was found that $436 \text{ m}\mu$ excitation produced blue luminescence of intensity similar to that at room temperature. This is explained by liberation of holes by light (the usual thermal liberation mechanism is not effective at low temperatures) which then ionize the blue centres. The process of luminescence and ionization of the blue centres by holes is called "anti-Stokes sensitization". There are three figures and seven references, four of which are Slavic.

TITLE: On afterglow of Eu³⁺-ions in Phosphors Containing Thorium Oxide (O posle svechenii iona Eu³⁺ v fosforakh na osnove okisit toriya)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1957, Vol 21, #4, pp 505-506 (USSR)

ABSTRACT: Phosphors activated by tri-valence rare earth metal elements show line emission spectra due to forbidden electron transitions in the 4f-shell. In order to interpret these spectra, it is important to know the life-times τ of excitation states corresponding to each line.

Spectra of the phosphors ThO₂-Eu and Th(SO₄)₂ThO₂-Eu were investigated to find out the influence of the finite duration of an excited state on the afterglow of individual Eu³⁺-lines. A specially designed spark phosphoroscope made it possible to bring about pulse excitations with a duration of $\sim 10^{-5}$ sec and observe the afterglow from 3×10^{-4} to 4×10^{-2} sec after excitation cessation.

Card 1/2

48-4-9/48

TITLE: On afterglow of Eu³⁺-ions in Phosphors Containing Thorium
Oxide (O posle svezhenii iona Eu³⁺ v fosforakh na osnove
okisi toriya)

It was found out that individual phosphor lines fade in a different way. The brightness of some lines not only does not reduce after excitation cessation, but even increases during some time. This anomaly manifests itself especially strongly with the line of 590 m μ , the brightness of which rises by almost 50% during 2×10^{-3} sec after excitation cessation, and then begins a rather sharp fall.

This phenomenon can be used for determination of the τ -values for each line by examination afterglow curves.
The report was followed by a discussion.

TITLE: On the Quenching of ZnS-Cu, Co- and ZnS-Cu, Ni-Phosphors by Infra-Red Light (O tyshenii fosforov ZnS-Cu, Co i ZnS-Cu, Ni infrakrasnym svetom)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1957,
Vol 21, #4, p 538 (USSR)

ABSTRACT: Infra-red light gives rise to flashes and quenching of ZnS-Cu, Co and ZnS-Cu, Ni phosphors. It was discovered that at the constant intensity of infra-red light the phosphor brightness I depends on excitation intensity E according to the law:

$$I \approx E^{3/2}$$

The action of infra-red light in afterglow leads to the second-order hyperbola decay, instead of an exponential law as in the conventional scheme.

The stationary brightness and decay of the phosphors were calculated for a case when holes in the valence zone have a greater probability to return to luminescent centers than to recombine with localized electrons.

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1957,
Vol 21, #5, p 779 (USSR)

ABSTRACT: The paramagnetic resonance method was applied to determine
the valence state of an activator in crystallophosphors and
to detect the changes of valence during the excitation of
phosphors.

The paramagnetic resonance was investigated in the phosphors
SrS-Eu; CaF₂-Eu; SrS-Gd and SrS-Tb at the room temperature by
means of a superheterodyne radiospectroscopic. It was established
that Eu in phosphors is in bivalent state (Eu^{2+}), and
Gd and Tb are in the trivalent states (Gd^{3+} and Tb^{3+}).

Card 1/2 The ratio of nuclear magnetic moments of Eu^{151} and Eu^{153}
nuclei was determined to be 2.24 ± 0.03 by observing the

TITLE: Effect of Temperature on Recombinational Interaction
of the Blue and Green Luminescence Centres in ZnS-Cu
Phosphor. (Vliyaniye temperatury na rekombinatsionnoye
vzaimodeystviye tsentrov goluboy i zelenoy lyumines-
tsentsii v fosfore ZnS-Cu.)

PERIODICAL: Optika i Spektroskopiya, 1958, Vol.IV, Nr.1,
pp. 118-121. (USSR).

ABSTRACT: Fok showed that (Ref.1) interaction of the blue and
green luminescent centre is due to exchange of holes
between them on excitation of the phosphor. Fok also
deduced formulae which give the steady-state brightness
of blue and green luminescence as a function of the
excitation intensity. These formulae were found for
the case when the exciting light is absorbed by centres
of one kind only. If the exciting light is absorbed by
Card 1/4 the blue centres, then at $C \ll 1$ the Fok formulae show

51-4 -1-24/26
Effect of Temperature on Recombinational Interaction of the Blue and Green Luminescence Centres in ZnS-Cu Phosphor.

that in a wide range of excitation intensities brightness of the blue luminescence (I') increases super-linearly with the excitation intensity E (up to $I' \sim E^{3/2}$). At the same time the green luminescence brightness I'' increases either linearly or sub-linearly with the excitation intensity. $C = \partial' w'' / \partial'' w'$, where ∂' and ∂'' are probabilities of capture of holes by the blue and green luminescent centres respectively, w' and w'' are the probabilities of liberation of holes by the same centres. From the Fok formulae it follows that on increase of temperature $I'(E)$ may become linear. To verify this the authors used ZnS-Cu phosphor with 10^{-7} g/g of the activator. The results of measurements of $I'(E)$ are given in Card 2/4 Fig.2, a. This figure shows that the blue luminescence

51-4-1-24/26

Effect of Temperature on Recombinational Interaction of the Blue and Green Luminescence Centres in ZnS-Cu Phosphor.

does indeed approach a linear dependence on the excitation intensity with increase of temperature. This in fact cannot be regarded as sufficient support for Fok's theory. The green luminescent brightness becomes superlinear in its dependence on the excitation intensity, contradicting Fok's theory (see Fig.2, b and Fig.3). This latter effect is due to excitation with $366 \text{ m}\mu$ which is absorbed by both blue and green centres. The authors solve kinetic equations for the case of absorption of the exciting light by centres of two kinds. The formulae then obtained gave better agreement with experiment in respect of non-linearity of $I''(E)$. The agreement between theory and experiment is still not completely satisfactory since the theory does

Card 3/4

51-4-1-24/26

Effect of Temperature on Recombinational Interaction of the Blue
and Green Luminescence Centres in ZnS-Cu Phosphor.

not predict the observed region of temperatures where
the brightness of both the green and blue luminescence
is a super-linear function of the excitation intensity.
This behaviour is ascribed to external quenching which
was not taken into account in calculations. There are
4 figures and 1 Russian reference.

AUTHORS: Georgobian, A.N. and Fok, M.V.

TITLE: Investigation of Relaxational Processes in Electroluminescence
(Issledovaniye relaksatsionnykh protsessov pri elektrolyuminestsentsii)

PERIODICAL: Optika i Spektroskopiya, 1958, Vol 5, Nr 2, pp 167-171 (USSR)

ABSTRACT: The authors studied relaxational processes in emission by an electroluminescent capacitor in order to elucidate the role of polarization charge in electroluminescence. This polarization charge is produced in separate grains of the phosphor (surrounded by a dielectric) by the action of the external alternating electric field. The magnitude and distribution of the polarization charge depend on the amplitude of the applied field, rate of change of this field and sometimes on previous history of the capacitor. The polarization charge distorts the field in the capacitor and concentrates it in a certain small region. Thus in an electroluminescent capacitor we have two regions: a region of high-field concentration and a field-free region. To study the processes occurring in these two regions the authors made some measurements on capacitors with ZnS-Cu₁Al phosphors. All measurements were made using symmetrical trapezoidal pulses of 200 c/s

Card 1/3

SOV/51-5-2-11/26

Investigation of Relaxational Processes in Electroluminescence

frequency, 300 V amplitude and the pulse-front slope of 1.42 V/ μ sec. The thickness of the capacitor was 0.2 mm. The authors investigated the form of brightness waves, the ratio between the alternating and constant components of electroluminescence as a function of the form of the trapezoidal pulses, the effect of red and infrared light on the form of brightness waves, and oscillograms of rise curves of electroluminescence. The ZnS-Cu-Al phosphors used had from 5×10^{-4} to 3×10^{-3} g/g of Cu, and from 3×10^{-4} to 2×10^{-3} g/g of Al. The phosphors were prepared at 1100°C in H₂S or at 1000°C in a mixture of H₂S and HCl. The following results were obtained. (A) The brightness waves had the form shown in Fig 1 (curves 1). Curves 2 in Fig 1 show the applied trapezoidal voltage pulses. (B) Mean brightness of luminescence depends on the amplitude and frequency of the applied field, and on the slope of the pulse-front (Fig 2). (C) The ratio of the constant and alternating components of electroluminescence depends both on frequency and the slope of the pulse front on the applied field and is practically independent of the field amplitude (Fig 3). (D) De-excitation with long-wavelength light has a stronger effect in phosphors which can store large light-sums and in this case only the constant component of electroluminescence is decreased. In phosphors which store small light-sums red light lowers

Card 2/3

SOV/51-5-2-11/26

Investigation of Relaxational Processes in Electroluminescence

also the alternating component. (E) When the alternating field is switched on the constant and alternating components of electroluminescence grow at different rates (the constant component grows more slowly as shown in Fig 4). The authors give the following tentative explanation for the observed behaviour of ZnS-Cu-Al. The field-free region in the capacitor extends throughout most of the capacitor and the region of high field concentration is near the electrodes. The alternating component of electroluminescence arises from liberation and subsequent recombination of electrons in the high-field region. The constant component of electroluminescence is due to processes affecting holes and electrons, which occur in the field-free region. There are 4 figures and 3 Soviet references.

TITLE: The Effect of the Stored Light-Sum on the Brightness of Electro-Luminescence of the ZnS-Cu_xAl Phosphor (Vliyaniye zapasennoy svetosummy na yarkost' elektrolyuminestsentsii fosfora ZnS-Cu_xAl)

PERIODICAL: Optika i Spektroskopiya, 1958, Vol 5, Nr 2, pp 172-178 (USSR)

ABSTRACT: The paper gives new experimental data on dependence of the brightness of electroluminescence on the light-sum stored in the phosphor. The authors followed the technique developed at the Luminescence Laboratory of the Physica Institute of the Academy of Sciences of the U.S.S.R. by Z.A. Trapeznikova and R.M. Medvedeva, who prepared phosphors which store large light-sums when excited with electric fields. These phosphors were prepared in an atmosphere of H₂S and HCl. Electroluminescent capacitors were prepared from such phosphors by pouring out a layer of ZnS-Cu_xAl mixed with melamideformaldehyde and alkyd "Rezyl" (trade name) resins onto conducting glass plates. Such a layer was dried and polymerized and a film of aluminium was deposited in vacuum to serve as the second electrode. Measurements were made from -195°C to +100°C using fields of 450 V and 3000 c/s. 366 m μ mercury line was used as a source of excitation in some of the experiments.

The Effect of the Stored Light-Sum on the Brightness of Electroluminescence of
the ZnS-Ga₂Al Phosphor

The results obtained are shown schematically in Fig 1. At room temperature (the upper part of Fig 1) the electroluminescent brightness increases from the moment of switching on the field and in 6-8 min reaches a steady-state (Fig 1, 1a). If, with the field on, the phosphor is irradiated with infrared light, then the brightness falls (Fig 1, 1b). The increase of brightness is accompanied by an increase in the light-sum stored in the phosphor. This was checked by measurement of flash brightness under the action of infrared light (the thick vertical lines in Fig 1 are proportional to such flash brightness). If, with the field on, the phosphor is irradiated with ultraviolet light (366 m μ), then a rise of brightness above the previous steady-state value is obtained (Fig 1, 1v). If, after this new steady state is reached the ultraviolet irradiation ceases, then the brightness falls very slowly to the steady-state value obtained with the field alone (Fig 1, 1g). Decay of phosphorescence (Fig 1, 1e) excited by ultraviolet light without the field (Fig 1, 1d) proceeds faster than the decay of brightness

produced by the simultaneous action of ultraviolet light and the field. This means that the increase of electroluminescent brightness by the action of ultraviolet light cannot be explained by the additional effect of phosphorescence. The light-sum reaches its maximum value under the action of the field and ultraviolet light. At room temperature, the presence of a stored light-sum increases the electroluminescent brightness irrespective of whether this light sum was stored by means of the field or ultraviolet light. At low temperatures the behaviour of the phosphor is the converse of that observed at room temperature (Fig 1, 2a-e), i.e. the presence of a light-sum in the phosphor lowers the electroluminescent brightness irrespective of whether this light-sum was stored by the action of the electric field of ultraviolet light. The authors discuss the following possible explanation (due to V.V. Antonov-Romanovskiy) for the anomalous behaviour of the ZnS-Cu,Al phosphor at low temperatures. At such temperatures the localized electrons increase the scattering and absorb the energy of free electrons which are moved by the electric field. The mean free path of the free electrons is shortened and

their energy decreases. This means that the probability of ionization
of luminescence centres by the free electrons decreases. As a result
the electroluminescent brightness decreases without any marked decrease
in the amount of energy absorbed. There are 4 figures and 4 references,
3 of which are Soviet and 1 French.

of Holes in ZnS-Cu and ZnS-Cu, Co Phosphors

Orig Pub : Postepy fiz., 1958, 9, No 2, 197-209

Abstract : The calculation is given for a phosphor with two luminescent centers ("green" and "azure") and one electronic local level. Making certain assumptions concerning the probabilities of these transitions, it was possible to obtain results that are in good agreement with the experimental dependence of the intensity of luminescence on the intensity of excitation, the temperature dependences of the luminescence, and the course of quenching of the glow. Infrared extinction is explained on the basis of a simpler model, assuming a considerable probability of secondary capture of the hole by the luminescence centers.

TITLE: The Luminescence of Crystalline Phosphors and Its Application
(Lyuminestsentsiya kristallofosforov i yeye primeneniye)
All-Union Conference in Moscow (Vsesoyuznoye soveshchaniye v
Moskve)

PERIODICAL: Vestnik Akademii nauk SSSR, 1958, Nr 11, pp 121-122 (USSR)

ABSTRACT: The Seventh Conference was held in Moscow from June 26 to July 3 and had been convened by the Fizicheskiy institut im. P. N. Lebedeva Akademii nauk SSSR i Nauchnyy sovet po lyumines-tsentsii (Institute of Physics imeni P. N. Lebedev of the AS USSR and the Scientific Council for Luminescence). Almost 350 delegates from the Soviet Union, as well as a few foreign scientists attended the conference. Approximately 100 reports were given. The majority of the talks dealt with the luminescence of alkali-haloid crystalline phosphors. Reports were given by:
F. D. Klement, I. A. Parfianovich, L. M. Shamovskiy, M. L. Kats, Ch. B. Lushchik and others on the Kinetics of Luminescence of These Phosphors, the Exiton and Ion Processes Taking

TITLE: On the Simultaneous Action of Photo- and Electro-Excitation on Electrophosphors. (Ob odnovremennom deystvii foto- i elektrovozbuzhdeniya na elektrolyuminofory)

PERIODICAL: Optika i spektroskopiya, 1959, Vol 7, Nr 2, pp 241-243 (USSR)

ABSTRACT: The authors found that photo- and electro-excitation are not additive: in some cases the luminescence brightness due to simultaneous excitation was higher and in other cases it was lower than the sum of the brightnesses of both types of luminescence. The former situation was called the positive non-additivity, the latter - the negative non-additivity. By altering the conditions of excitation one could alter the positive non-additivity into the negative non-additivity and conversely. At a certain ratio of the photo- and electro-excitation intensities exact additivity could be obtained: this is shown by the straight line in Figs 1 and 2. In two ZnS-Cu,Al phosphors the maximum observed non-additivity amounted to ~10%. Phosphor Nr 1 (cf Fig 1) stores a small light-sum at room temperature. Its photoluminescence brightness depends non-linearly on the intensity E of the exciting light: the brightness is proportional to $E^{3/2}$ which indicates strong external quenching. The phosphor Nr 2

Card 1/2

SOV/51-7-2-15/34

On the Simultaneous Action of Photo- and Electro-Excitation on Electrophosphors

(cf Fig 2) stored a considerable light-sum and its photoluminescence brightness was almost exactly proportional to the excited light-intensity indicating that in this case external quenching was small. Figs 1 and 2 show clearly that the ratios of the electrical field and the light intensity required to achieve exact additivity are quite different in the case of the two phosphors. The causes of the observed behaviour are discussed and it is shown that the condition of the exact additivity is given by

$$\alpha_e/\alpha_l = \text{const.},$$

where α_e and α_l are the number of acts of ionization of luminescence centres per unit volume and per unit time due to the electric field and the light respectively. There are 2 figures and 5 Soviet references.
